

Spatial attention is modulated by representational formats of spatial direction

Adam J. Barnas, Natalie C. Ebner, & Steven M. Weisberg

Introduction

Visual navigation cues support spatial navigation abilities

Spatial direction is extracted faster for schemas and words than scenes¹

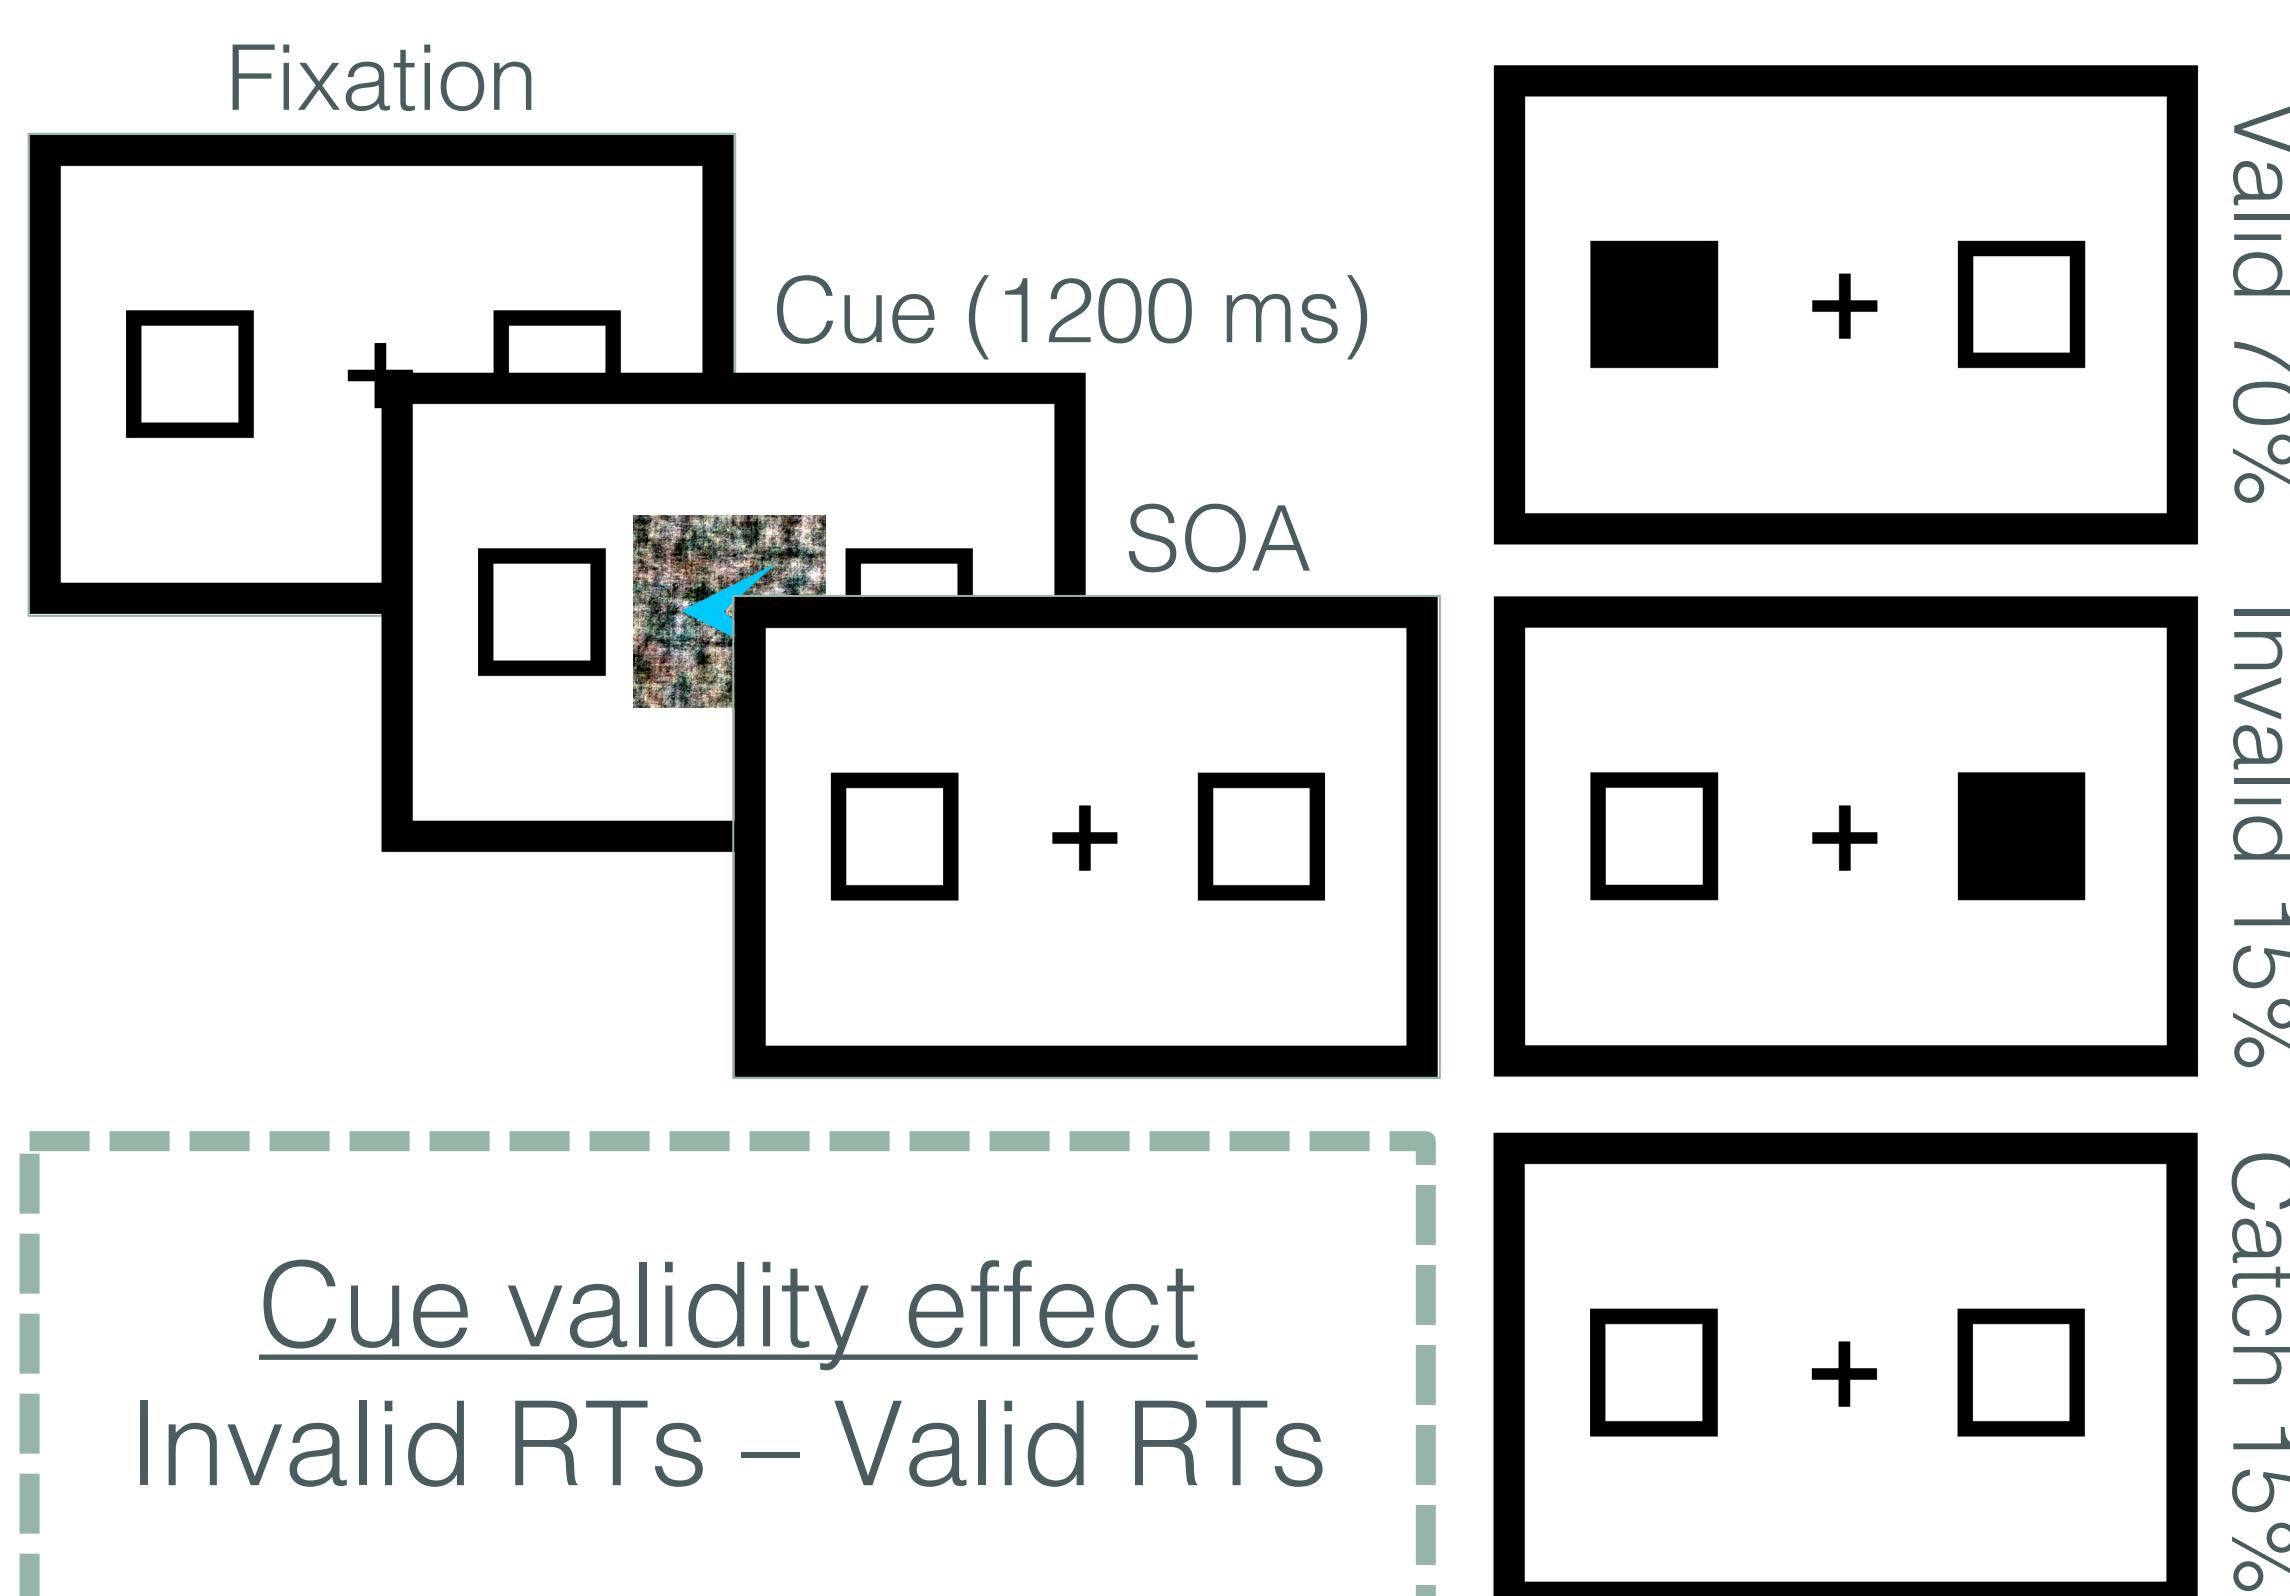

Is attention responsible for differences in extracting spatial direction?

Task

Directions: ahead, left, right
Formats: scene, schema, word

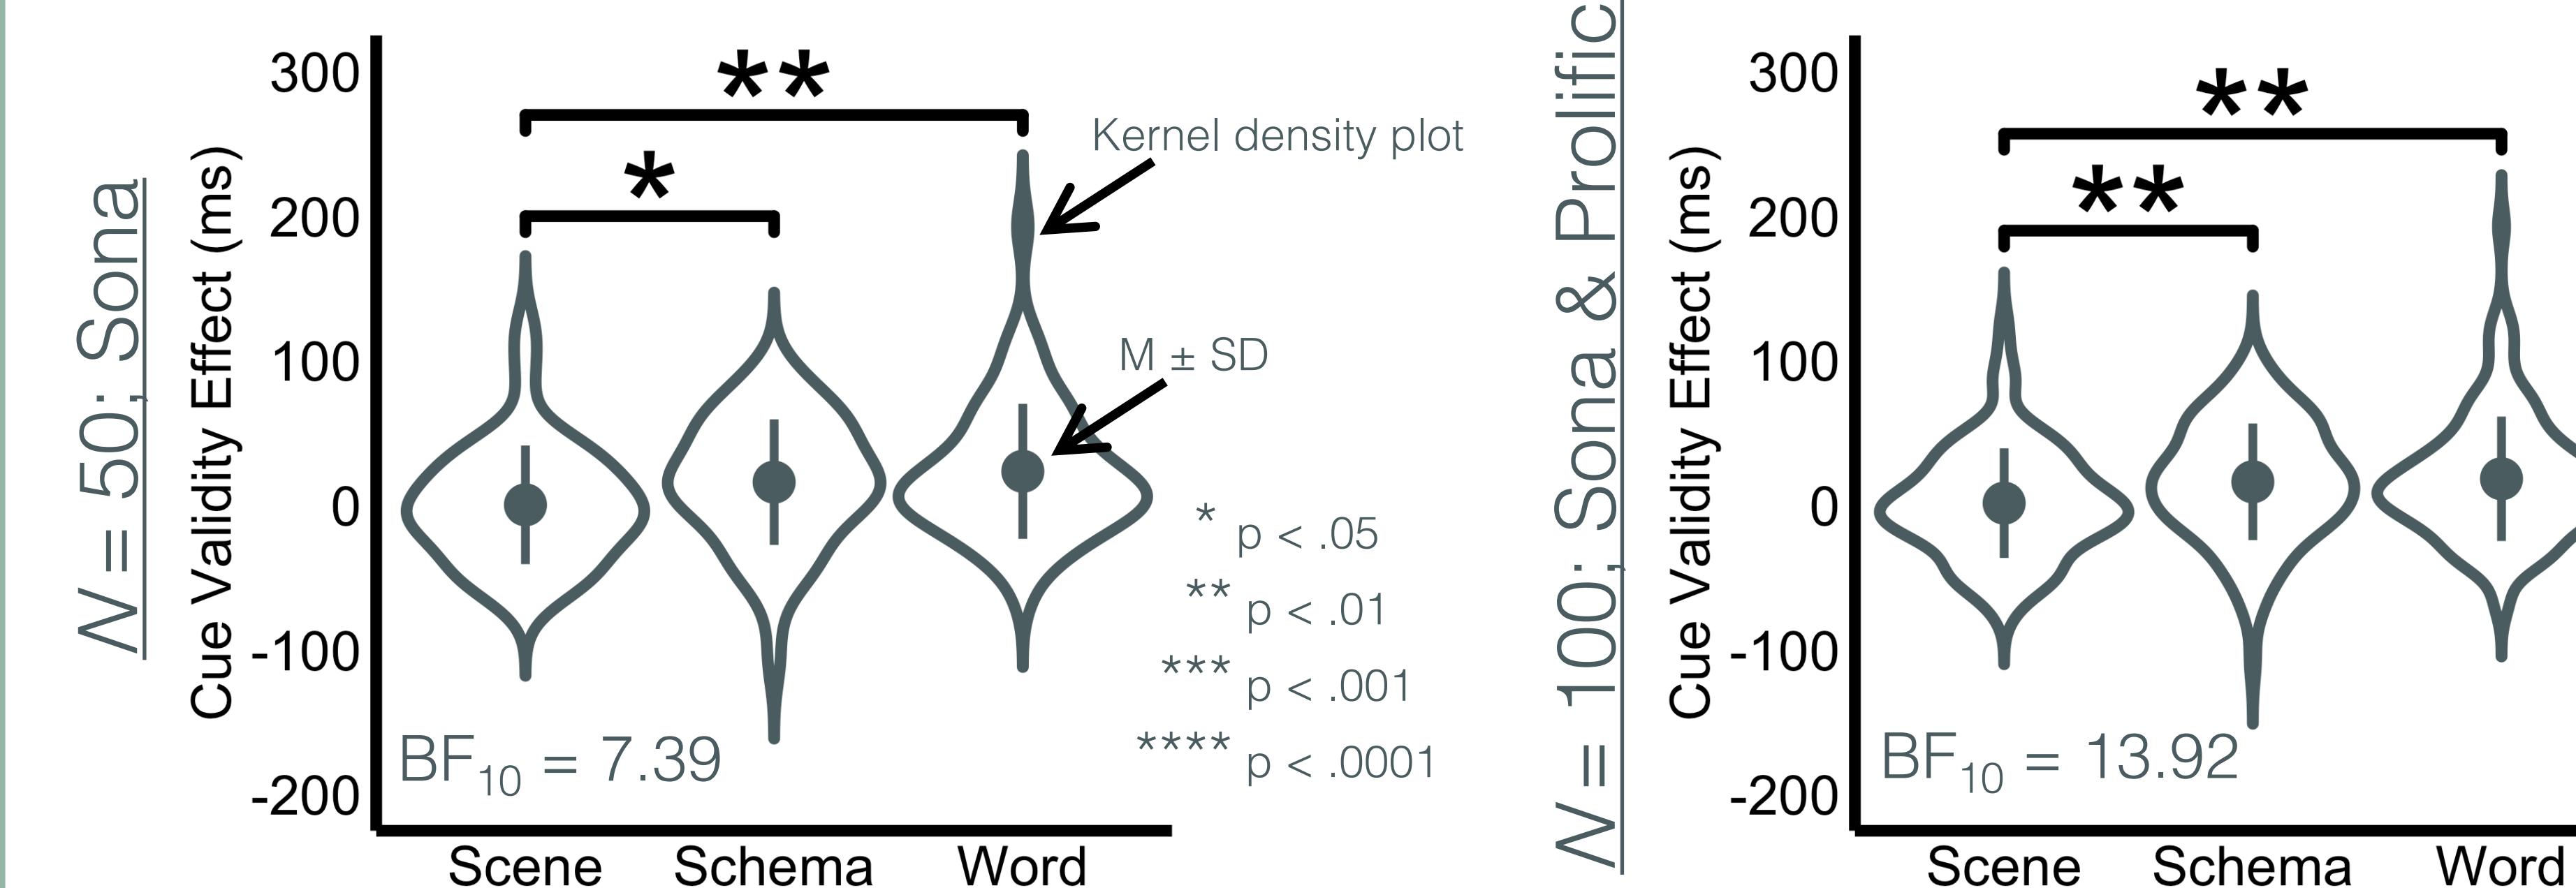

Spatial Cuing Paradigm²

Exp 1: Cue format

H1: Cue validity effects will be larger for schemas and words than scenes

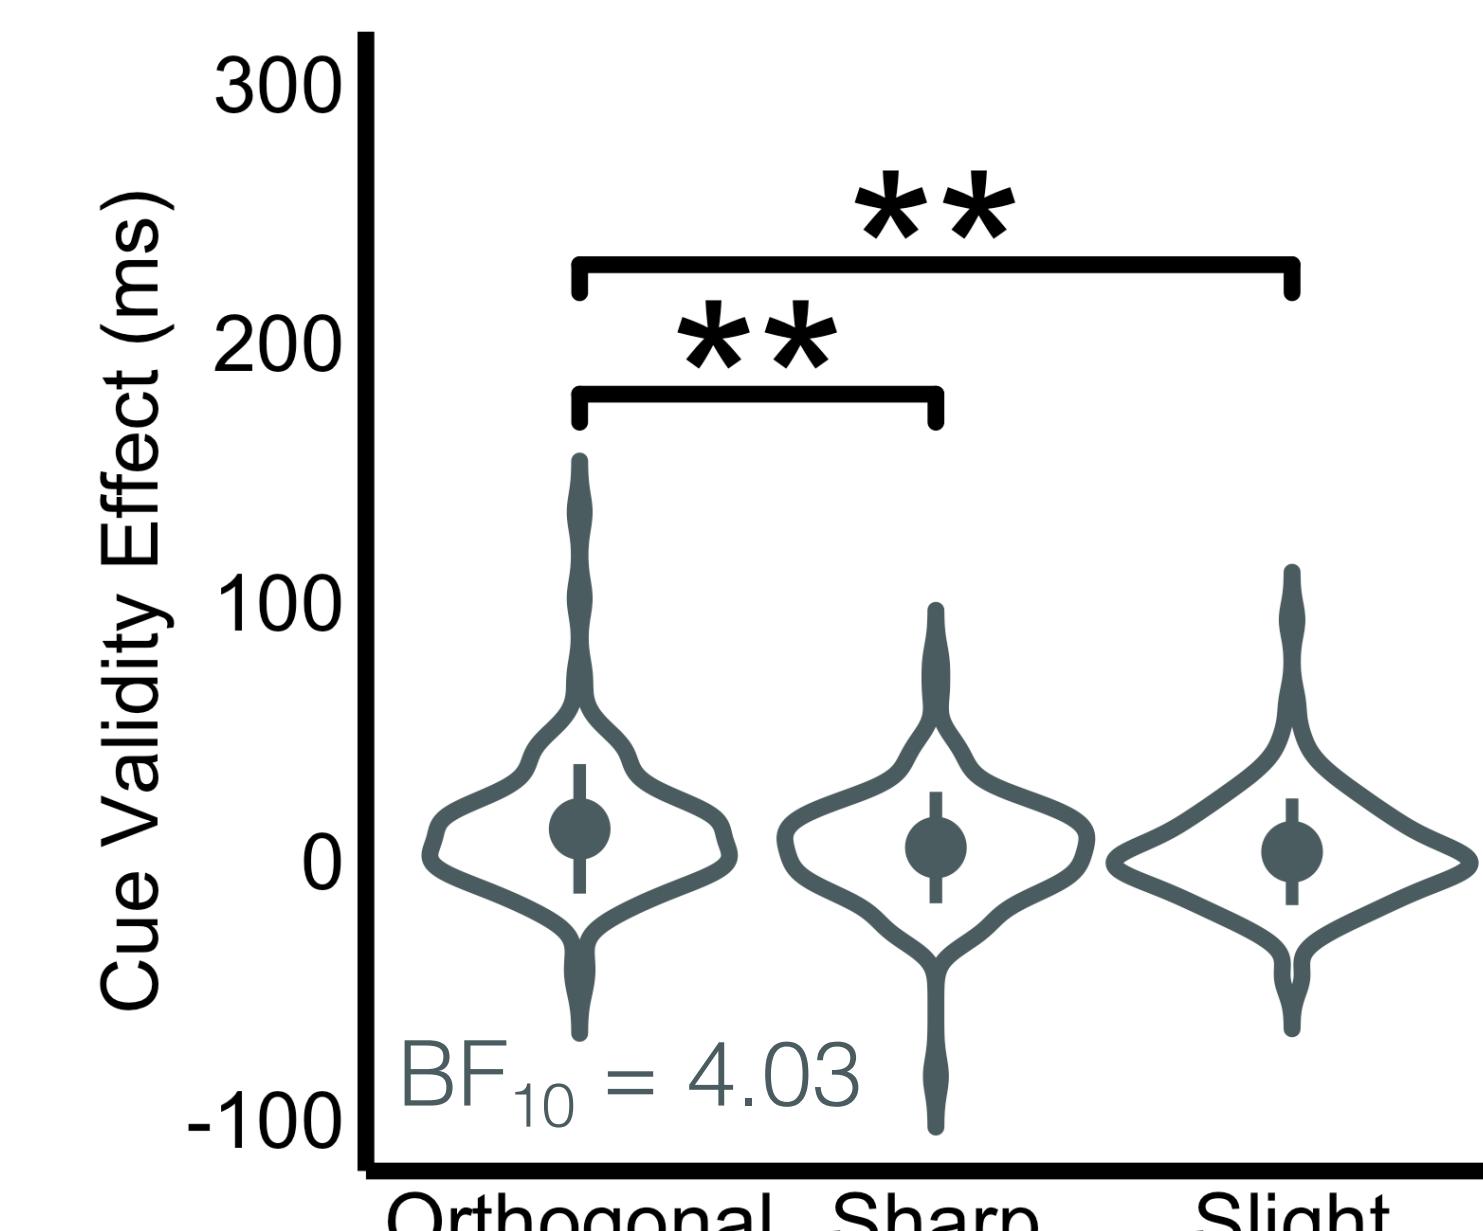

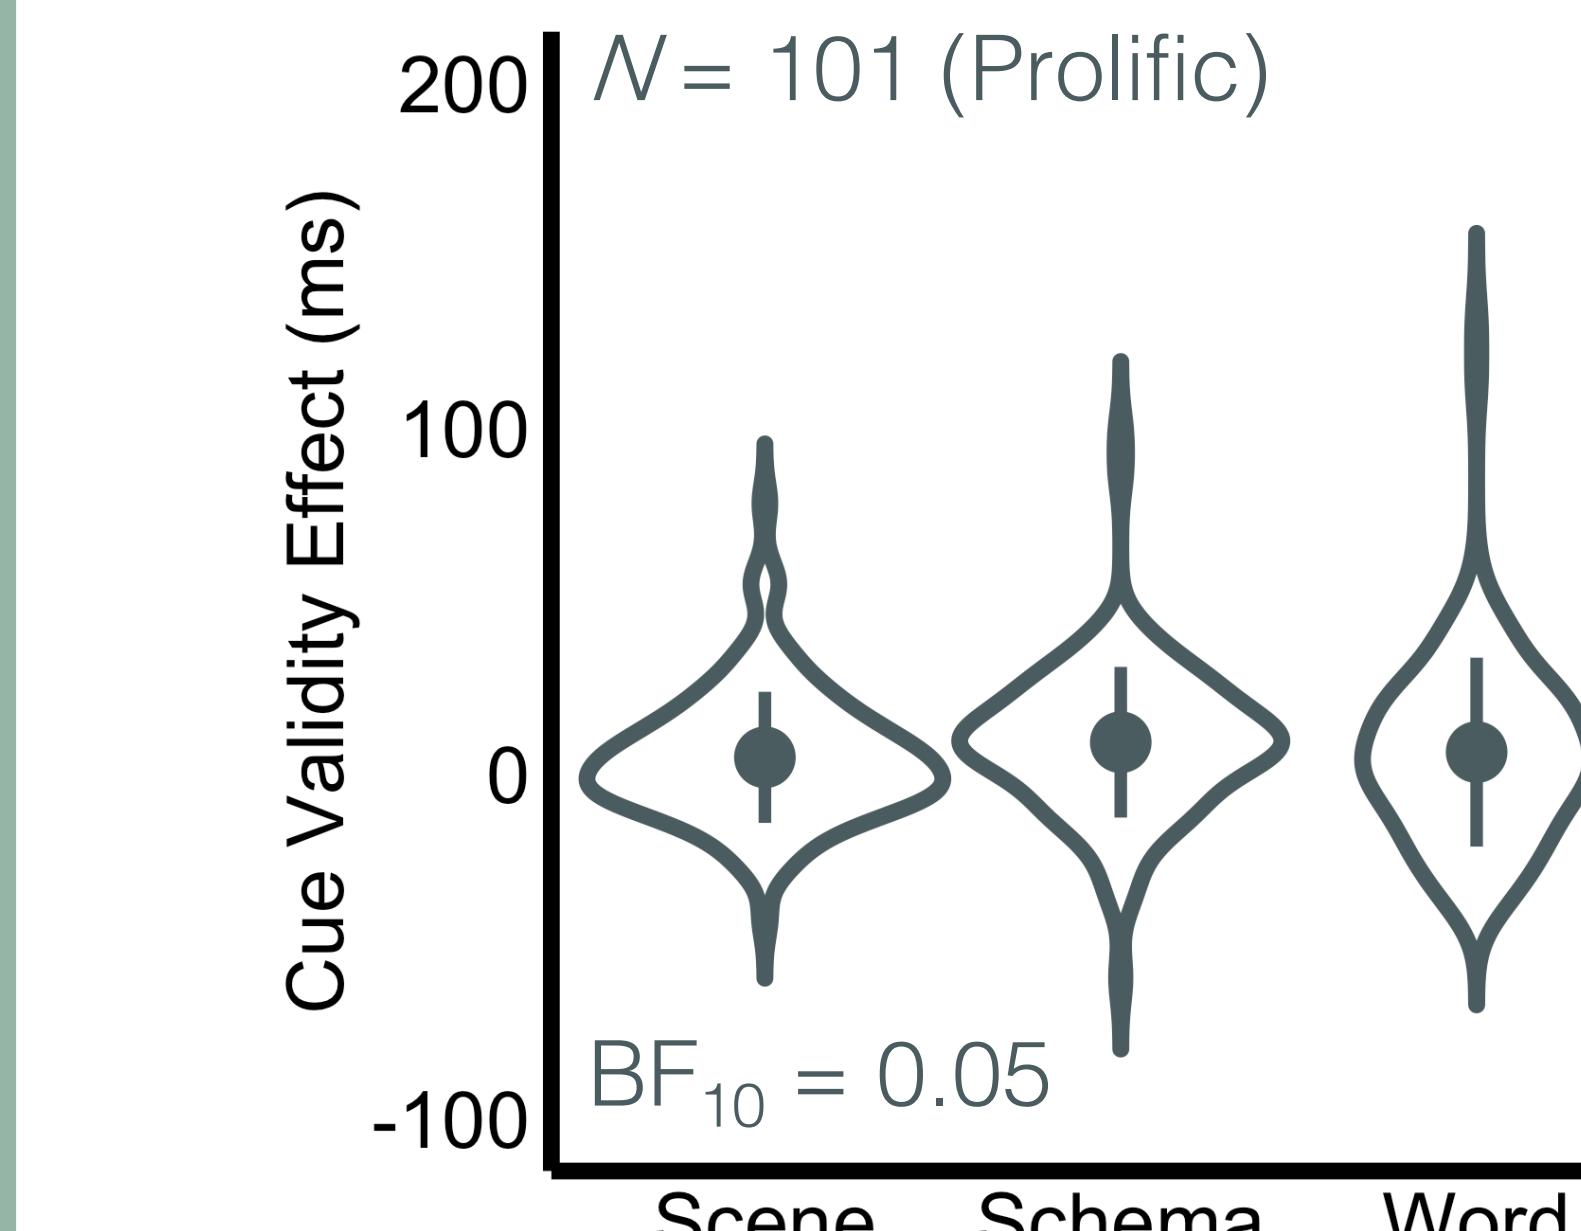

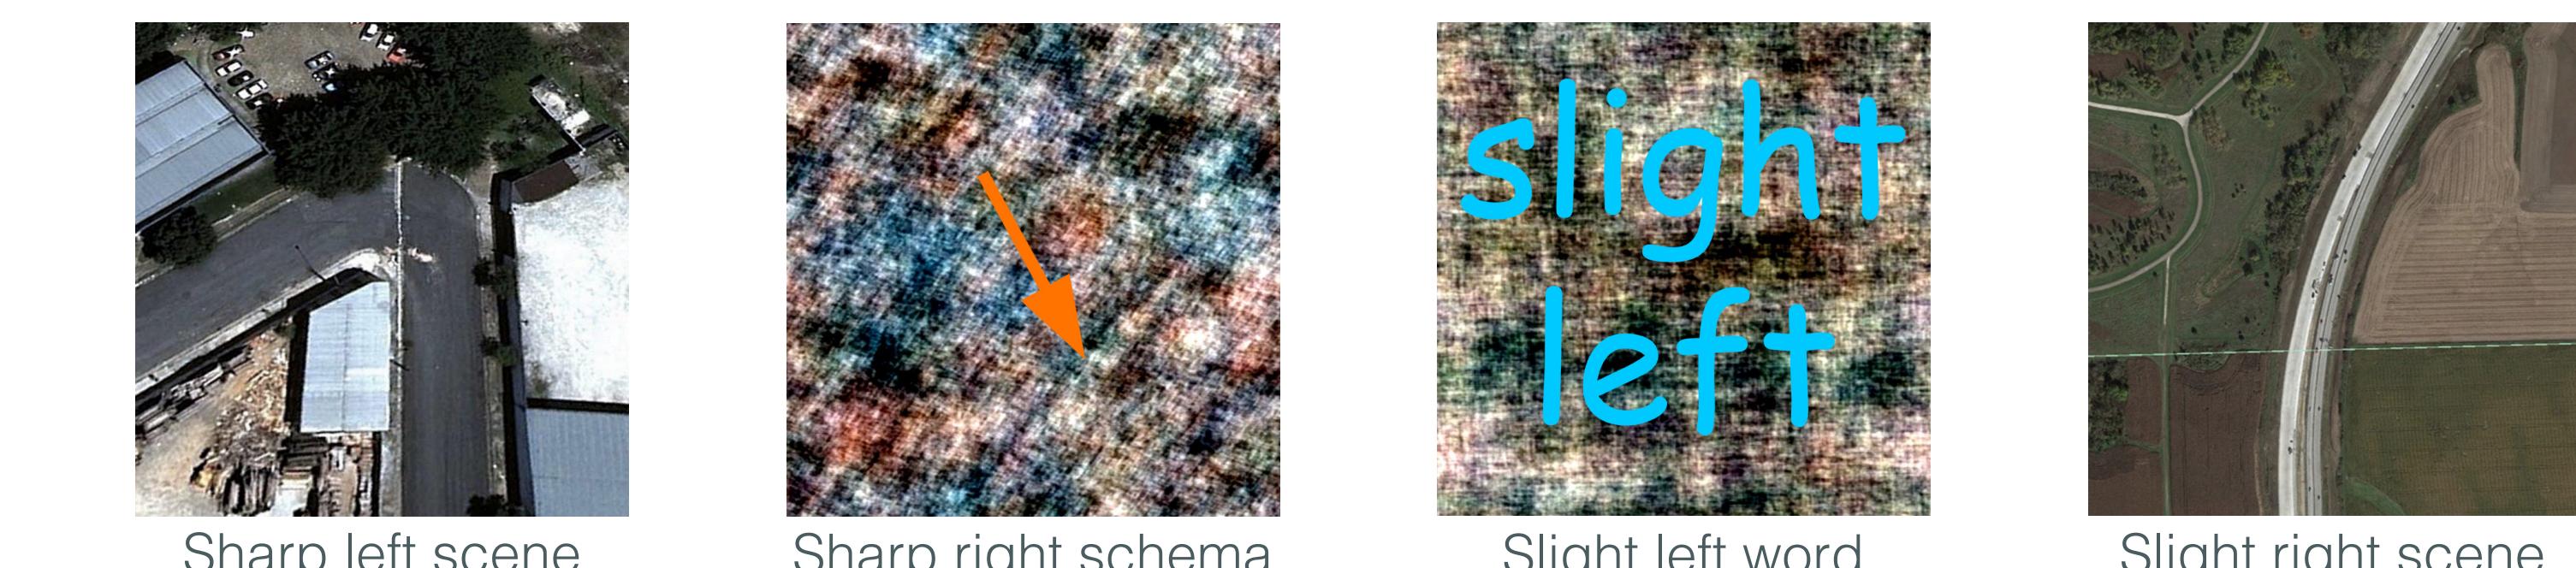

Larger cue validity effects for schemas and words than scenes

Scenes require more costly computations to decode direction

No effect of recruitment method (Sona vs. Prolific; $N = 50$ each)

Exp 3: Cue angle

H3: Cue validity effects occur for orthogonal, not sharp or slight cues
Additional directions: sharp left, sharp right, slight left, slight right

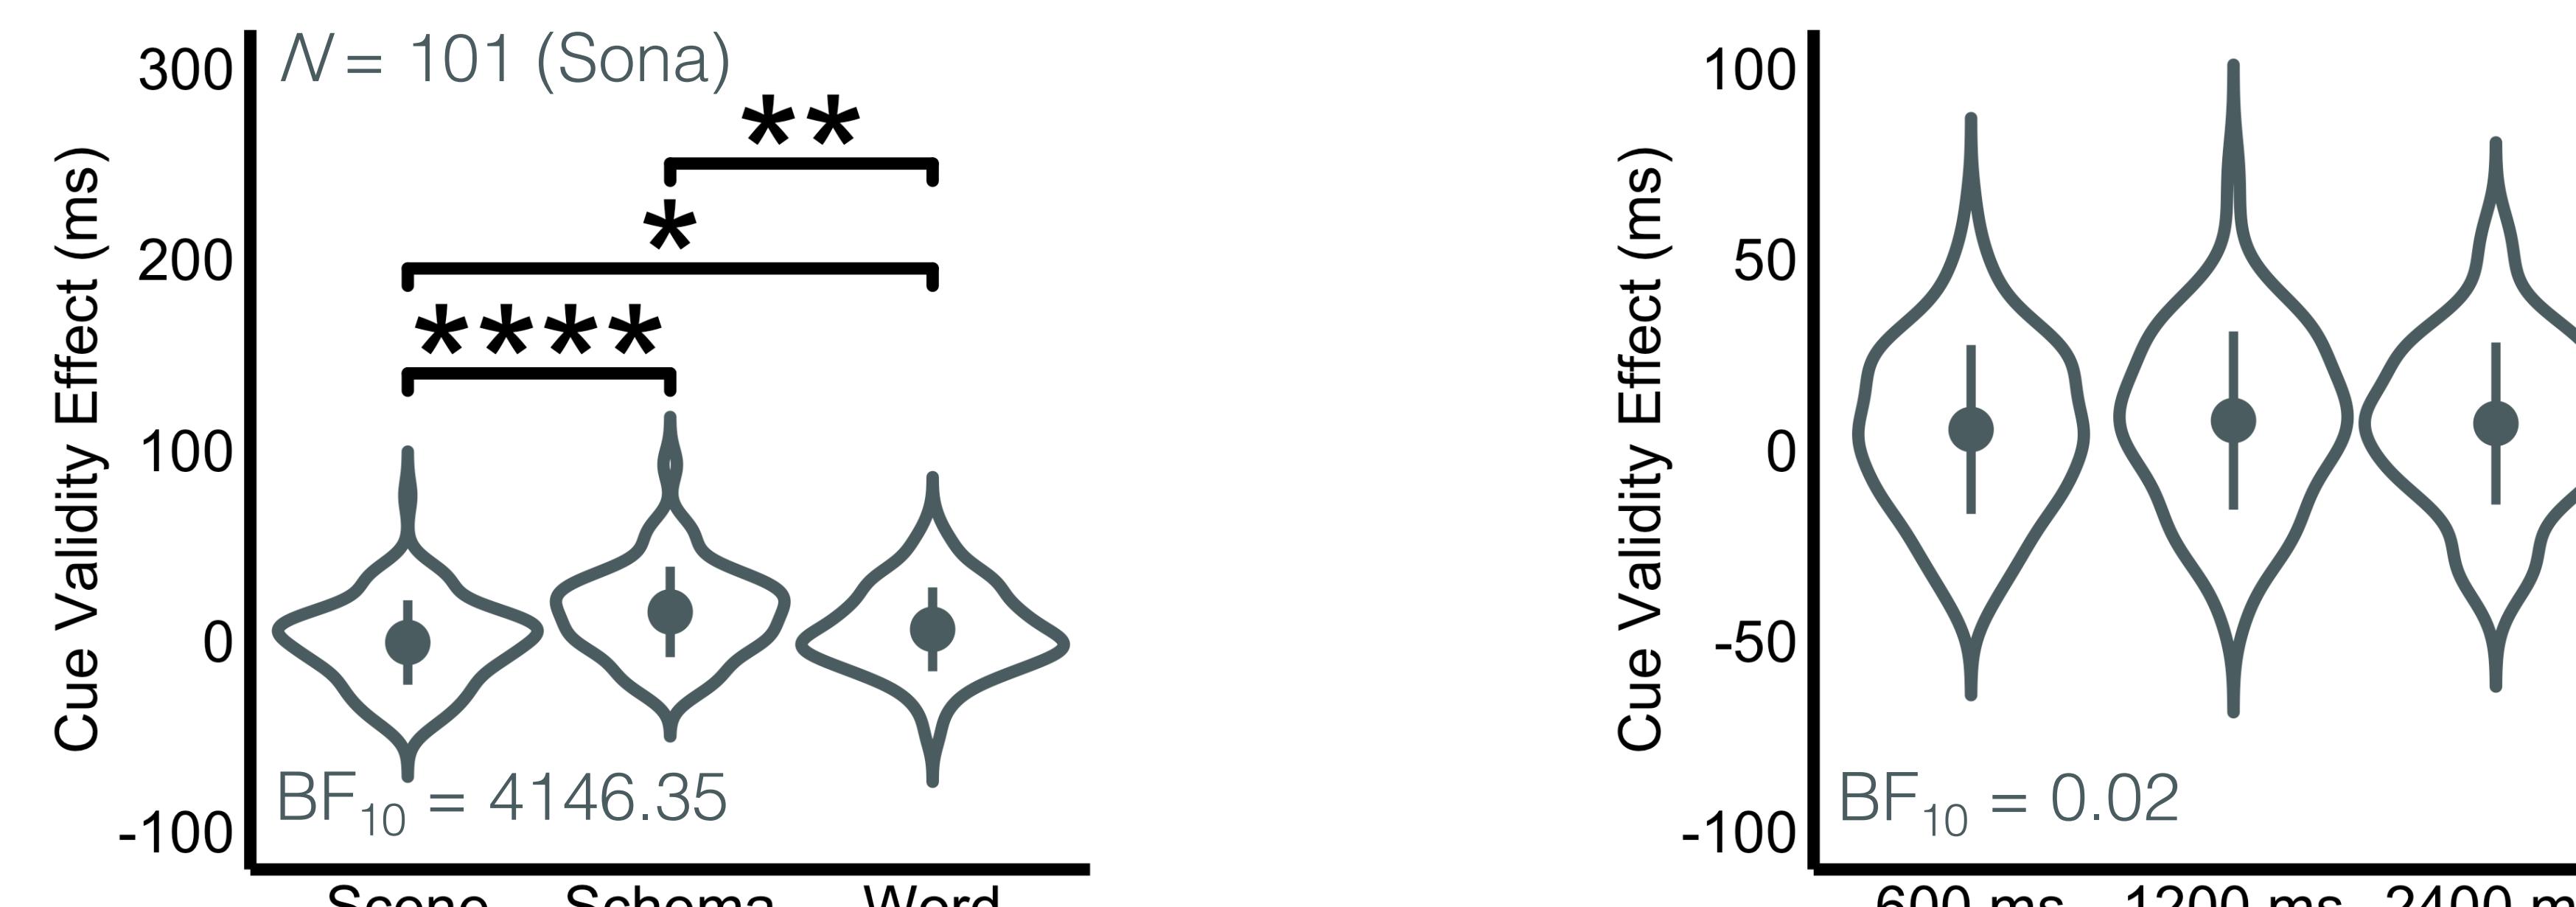

Larger cue validity effect for orthogonal cues than sharp and slight cues

Non-orthogonal cues may engage attention differently

No effect of cue format

Exp 2: Cue duration

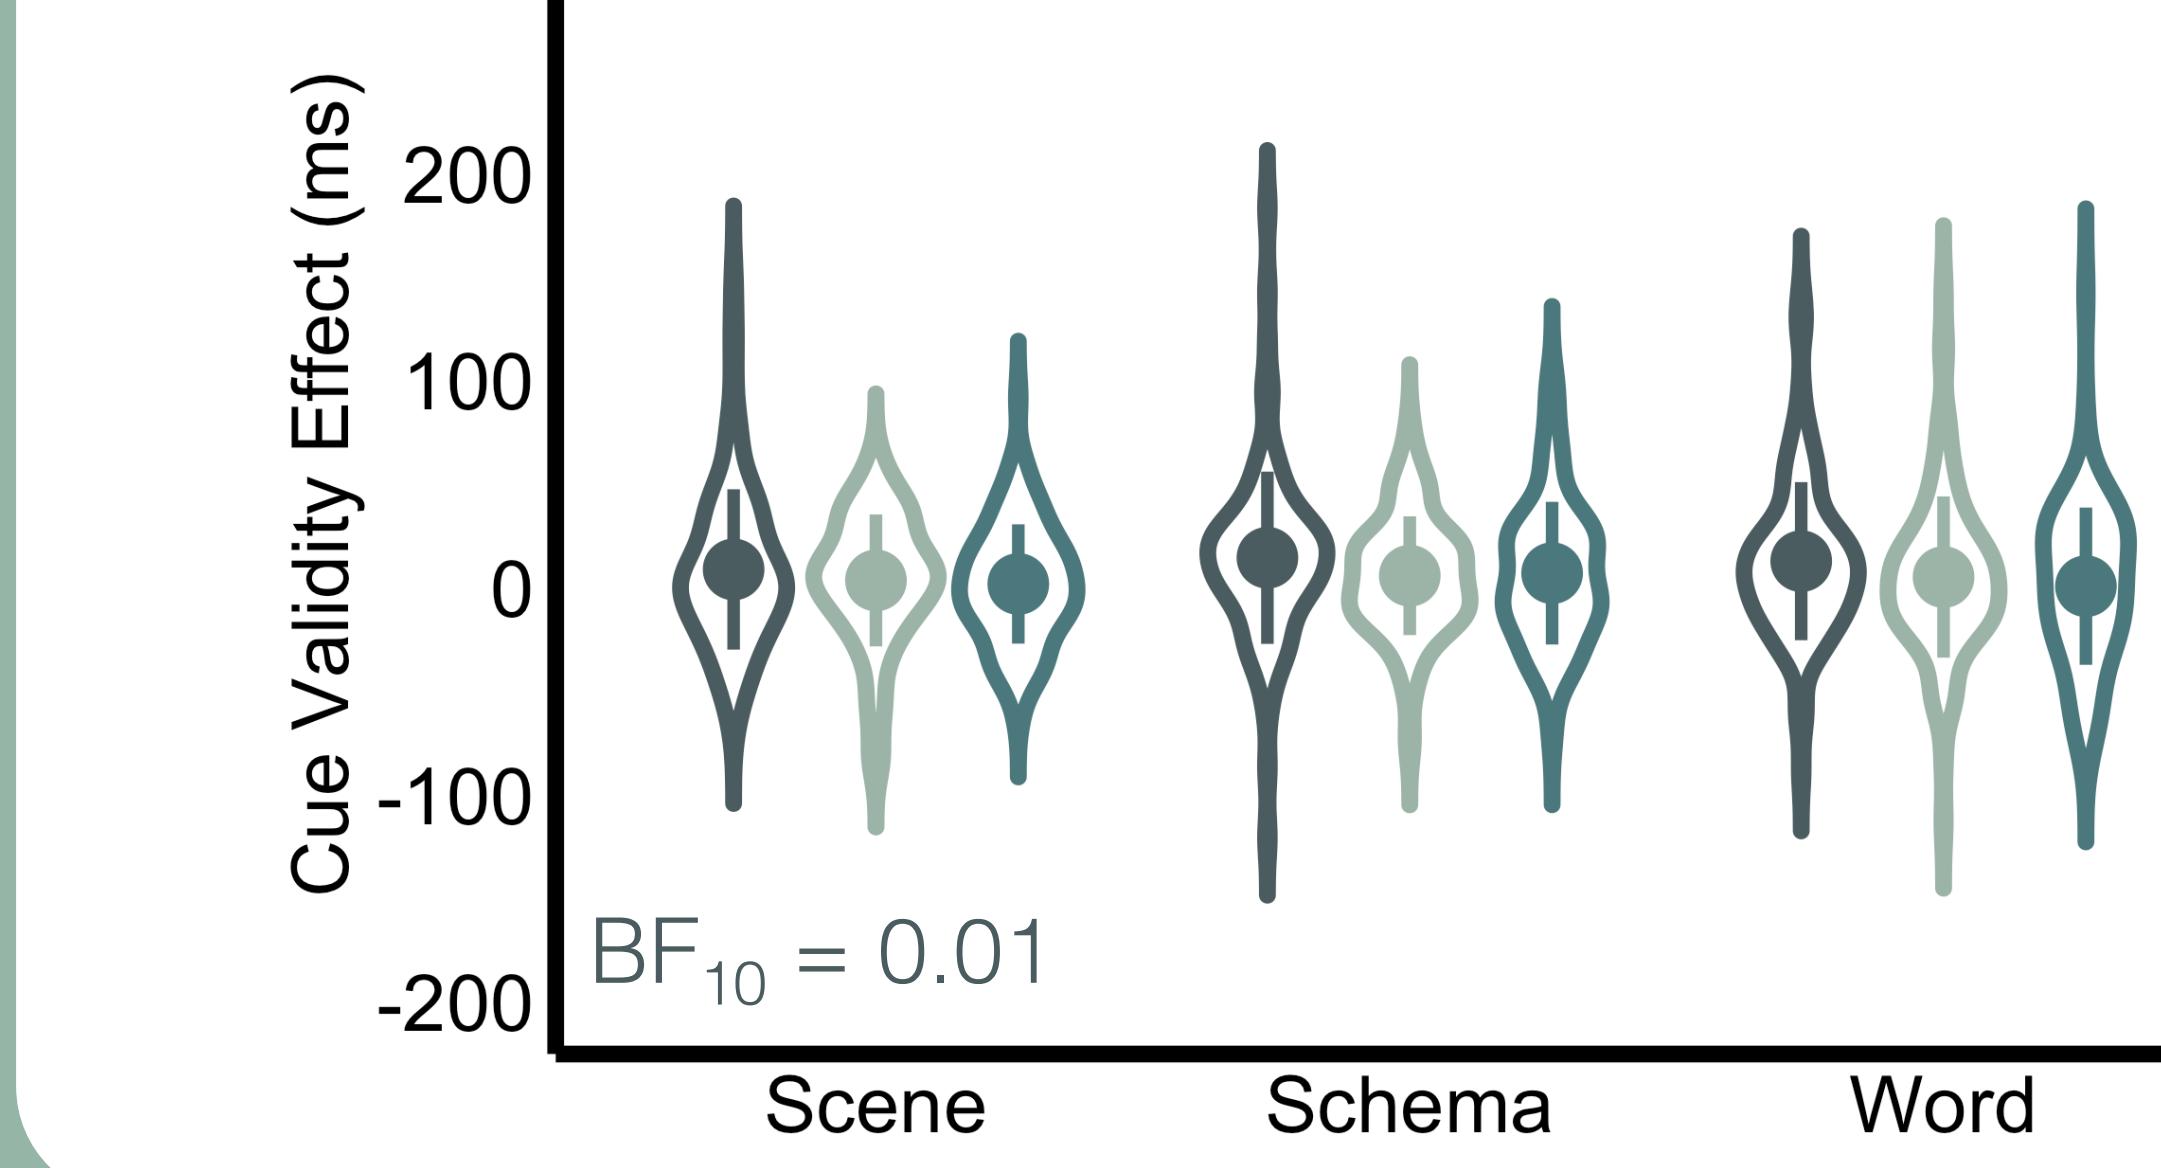

H2: Longer cue duration will result in cue validity effect for scenes

No effect of cue duration regardless of cue format

Increasing cue duration did not enhance spatial attention

Exp 1 replicates: Larger cue validity effects for schemas and words than scenes

Conclusion

Attention is allocated more efficiently with schemas and words, which may explain why direction is extracted faster for these formats

Schemas and words may be more effective supports for navigation
